

Name of Student ----- Enrolment No. -----

Department / School -----

BENNETT UNIVERSITY, GREATER NOIDA

End Term Examination, Fall SEMESTER 2019-20

COURSE CODE: ECSE105L

MAX. DURATION: 2 Hours

COURSE NAME: Computational Thinking and Programming

MAX. MARKS: 30

Note :

- All the questions are compulsory.
- No Separate answer sheets will be given. Answer in the space provided.
- Read each question carefully before answering.
- Please write precisely and neatly. Please make clear diagram wherever required.

MULTIPLE-CHOICE QUESTIONS

[4 × 1= 4 Marks]

Q.1. Which function return current position of file pointer?

- | | |
|-----------|------------|
| a. seek() | c. tell() |
| b. read() | d. write() |

Q.2. Once you open a file with a+ mode, where will be the position of file pointer?

- | | |
|--------------------------|-----------------------|
| a. End of file | c. No fix positions |
| b. Beginning of the file | d. Middle of the file |

Q.3. Which function used to find number of elements in a tuple?

- | | |
|-----------|------------|
| a. find() | c. pop() |
| b. len() | d. split() |

Q.4. what will be the result of following expression?

14.5%6 or 21

- | | |
|--------|----------|
| a. 4.5 | c. 21 |
| b. 2.5 | d. Error |

CONCEPTUAL QUESTIONS

[4 × 1= 4 Marks]

Q.5. Write one word/line answer.

- a. Which access mode in file handling can create a new file?
- b. In which data structure all elements are unique?
- c. What is the way to get list elements in ascending order?
- d. How you will write a class when Class A is parent and Class B is child class (syntax only).

[3 Marks]

Q.6. We know that every concept in the programming language has a special meaning towards it. Justify why we have two different types of loops (**while** and **for**) in python? Illustrate their speciality with an example.

[3 Marks]

Q.7. Assume that you are working for a software industry and your manager wants you to develop a small module to handle two situations for a multiple-choice quiz (with four options) software that is under development.

- Only one option is correct. Don't check further.
- More than one option is correct. Hence, check for each option.

Write an *if*, *elif* and *else* code structure to handle each situation separately.

[4 × 1 = 4 Marks]

- Q.8. As discussed in classroom, industries often rely on reading a software code by a new developer before moving forward with any modifications/updates. Hence, reading and understand the code is a key task for a successful software product. Your manager in the industry asks to you comprehend/read the portion of the codes and suggest the output.

	Code	Output
a	<pre>def myfun(L): L[0][:]=[5,6,7] L[1]=20 print(L) return L X=[[1,1,1],[2,2,2],[3,3,3]] myfun(X[:]) print(X)</pre>	
b	<pre>with open('abc.txt', 'w+') as fp: fp.write("Hello this is final exam.\n") fp.write("Best wishes for next semester.") fp.seek(0) print(fp.read(5)) fp.readline() print(fp.read(5)) for x in fp: print(x)</pre>	
c	<pre>class A: def __init__(self): self.x=2 class B(A): def __init__(self): self.y=3 b=B() print(b.y) print(b.x)</pre>	
d	<pre>A = {1, 2, 3, 4, 5} B = {4, 5, 6, 7, 8} print(A B) print(A - B) print(A.difference(B))</pre>	

PROGRAMMING QUESTIONS

[3 Marks]

- Q.9. In a real-world software development, one module can have multiple functions/methods/operations (all three are the same) are created by the developer that work with each other to achieve the objective of the module.

Your manager asked you to develop a function in Python named "MYFUNCTION" that accepts two lists both of which contain integer elements and returns a sorted list (ascending order) which contains unique common elements from both the lists. If

there are no common elements between the two lists, then your function should return the keyword- **None**

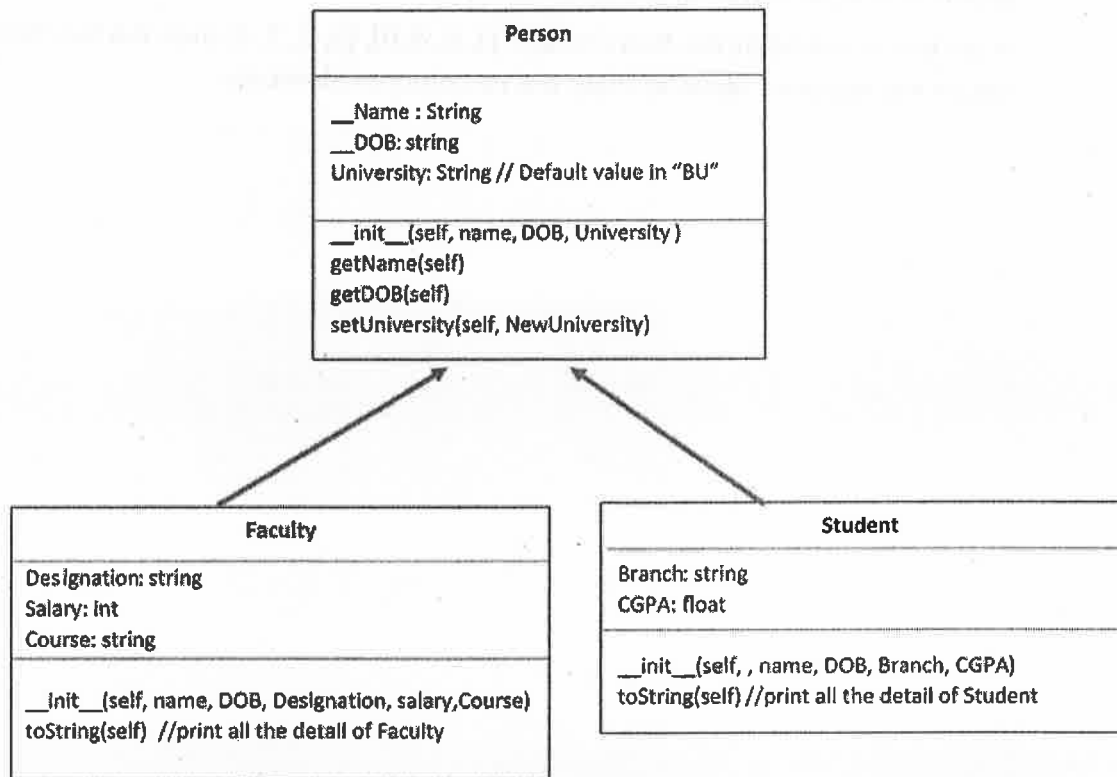

Example: Two list that is accepted by the function are: [2,4,3,6,7,8,3], [2, 8, 8, 3, -7]. Here, elements 2, 3, and 8 are common in both the first lists as well as 3 in the first and 8 in the second list occur twice. Now the function returns a sorted list (ascending order) of unique common elements: [2, 3, 8]

If the lists received by the function are: [1, 6, 4, 0], [3, 2, 3, 2] then the function should return the keyword **None** as there are no common elements.

[4 Marks]

Q.10. Before development of the actual software product in the industries, there exists planning of the development. One of the stages requires diagrams to be created. From the diagrams, developers get a snapshot of the entire module and can develop the code. Below is the class diagram of the module from that you have to construct a code skeleton (don't write function implementation details).

[5 Marks]

Q.11. Everyone has heard a song or knows what a song sounds like. A song is typically intended to be sung by the human voice with distinct and fixed pitches and patterns using sound and silence and a variety of forms that often include the repetition of sections.

Develop a python code to answer the following scenarios:

- How many unique words were used compared to the whole lyrics of in the given song?
- What are the top 5 most repetitive words used and how many times they were used throughout the song?

Input: Lyrics file of given song in "song.txt" file

Output: Number of unique words, Top 5 most repetitive word in a dictionary.
